

1

WPH(**Water Per Hour**): Theoretical unit throughput by recipe
Peak WPH: The throughput under **continuous run status**

$$\text{WPH_Ratio\%} = \frac{\text{Actual WPH}}{\text{Average Peak WPH}}$$

2

$$\text{Actual WPH} = \frac{\sum_{n=1}^b \text{Move of recipe}_i}{\sum_{i=1}^n \text{Actual production time by recipe}_i}$$

3

Average Peak WPH

$$4 = \frac{\sum_{i=1}^n \text{Move of recipe}_i}{\text{Theoretical production time by recipe}_i} = \frac{\sum_{i=1}^n \text{Move of recipe}_i}{\sum_{i=1}^n \frac{\text{Move of recipe}_i}{\text{Peak WPH by recipe}_i}}$$

30m@6m/s

30m@6m/s

The average speed? $(6+3)/2=4.5\text{m/s}$? **X** $(30+60)/(20/6+60/3)=3.6\text{m/s}$? **✓**

Recipe 1: PWP 1=20, move 1=1000

Recipe 2: PWP 2=25, move 2=1500

Average PWP: $(1000+1500)/(1000/20+1500/25)=22.7$
